**Abstract:**

The filler injection for the aesthetic use is getting more and more popular over past decades. It has been used to correct the aging related problem over the face, including the sunken eyelid, nasojugal groove and even the insufficient height of nasal radix. However, iatrogenic blindness and skin necrosis remains the most devastating complication. We present a case who suffered from the skin necrosis, vision impairment and diplopia after the filler injection to the radix. During hospitalization, her visual acuity is quite improved surprisingly after the treatment. We would like to discuss the current treatment and review the up-to-date strategies of the filler related vision loss.
